### A Method and System to Soive Dynamic Multi-Factor Models in Finance

#### RELATED APPLICATION INFORMATION

This application claims the benefit of U.S. Provisional Application No. 66/378,562 filed on May 7, 2002. U.S. Provisional Application No. 66/378,562 is expressly incorporated lacent by reference in its eatherty into this application.

#### FIELD OF THE INVENTION

263

The present invention relates generally to systems and methods for estimating timetime varying factor exposures in financial or economic model or problem, through the solution of
a multi-factor dynamic optimization of the model or problem, while meeting the constraints
for the estimated time-varying factor exposures in the model or problem.

#### BACKGROUND OF THE INVENTION

#### A. Muiti-factor models in finance

Factor models are well known in finance, among them a multi-index Capital Asset Prices

Model (CAPM) and Arbitrage Pricing Theory (APT). These models allow for a large number
of factors that can infinance securities returned

The multi-factor CAPM, for example, described in Shame, William R., Capital asset prices: A theory of market emilibrium under conditions of risk, Journal of Finance, Sept. 1964, pp. 425-442, can be represented by the equation:

15

$$r - r^{(f)} \leq (L + \beta^{(f)}) (r^{(f)} - r^{(f)}) + \beta^{(2)} (r^{(2)} - r^{(f)}) + \dots + \beta^{(n)} (r^{(n)} - r^{(f)})$$
(1)

where r is the investment return (security or portfolio of securities),  $r^{(f)}$  are returns on the market portfolio as well as changes in other factors like inflation, and  $r^{(f)}$  is return on a risk-free instrument.

20

In the multi-factor APT model (described, for example, in Chen, N., Richard R., Stephon A. R., <u>Beonomic forces and the stock market</u>. Journal of Business, S9, Inty 1986, pp. 383-403):  $r = \alpha + \beta^{(1)} f^{(1)} + \beta^{(3)} f^{(2)} + \dots + \beta^{(n)} f^{(n)}, \qquad (2)$ 

the factors I<sup>G</sup> are typically chosen to be the major economic factors that influence security controls like inclusiving production in flation, interest state, business comb, atc. (Appendical, Eu-

returns, like industrial production, initiation, interest rates, business cycle, etc. (described, for example, in Chen, N., Richard R., Stephen A. R., Economic forces and the stock markel Journal of Business, 59, July 1986, pp. 383-403, and in Rosenberg, B., Choosing a multiple factor model. Investment Management Review, November/December 1987, pp. 28-35.

30 Coefficients \(\beta^{(0)}\_{\text{in}}\), \(\beta^{(0)}\_{\text{in}}\) in the CAPM (1) and APT (2) models are called factor exposures. Along with the constant \(\alpha\), \(\text{in}\) factor exposures make the vector of model parameters.

WO 93/696754 PCT/U883/35325

 $(\alpha, \beta^{(i)}, ..., \beta^{(i)})$ , which is typically estimated by applying a linear regression technique to the time series of security-portfolio returns  $\tau_i$  and economic factors  $\tau_i^{(i)}$  or  $\tau_i^{(i)}$  over a certain estimation whithout x = 1, ..., N:

5

16

$$(\hat{\alpha}, \hat{\beta}^{(1)}, ..., \hat{\beta}^{(n)}) = \underset{\alpha, \beta^{(n)}, \beta^{(n)}}{\operatorname{arg min}} \sum_{i=1}^{N} (r_i - \alpha - \beta^{(i)}) I_i^{(i)} - ... - \beta^{(n)} I_i^{(n)})^2$$
, (3)

One of the most effective multi-factor models for analyses of investment portibilion, called the Returns Based Style Analysis (RBSA), was suggested by Prof. William F. Sharpe (for example, in Starpe, William F., Latermining a Fund's Effective Asset Miz. Investment Management Review, November December 1988, pp. 59-69, and in Sharpe, William F., Asset Allocation: Management Style and Per formance Measurement. The Journal of Portfolio Management, Winter 1992, pp. 7-19). In the RBSA model, the periodic return y of a portfolio consisting of n kinds of assets is approximately represented by a linear combination of single factors ( $x^{(i)}, \dots x^{(o)}$ ) whose rule is played by periodic returns of generic market indices for the respective classes of assets. To enhance the quality of parameter estimation, a set of linear constraints is added to the basic equation:

$$y = \alpha + \beta^{(i)} x^{(i)} + \beta^{(2)} x^{(2)} + \dots + \beta^{(n)} x^{(n)}$$

$$\sum_{i=1}^{n} \beta^{(i)} = 1, \ \beta^{(i)} \ge 0, \ i = 1, \dots, n.$$
(4)

In such a model,  $x^{(i)}$ , i = 1,...,n, represent periodic returns (for example, daily, wookly or storethly) of generic market indices such as bunds, equities, aconomic sectors, country indices, currencies, etc. For example (as described in Sharpe, William F., Asset Allocation: Munassensen Style and Performance Measurement. The Journal of Partfolio Management, Winter 1992, pp. 7-19, twelve such generic asset indices are used to represent possible areas of investment.

25 To estimate the parameters of equation (4), Sharpe used the Constrained Least Squares Technique, i.e., the parameters are found by solving the constrained quadratic optimization problem in a window of t = 1,..., N time periods in contrast to the unconstrained one (3); WO 03/096354 PCT/1/903/16324

$$\begin{cases} (\hat{\alpha}, \hat{\beta}^{(i)}, ..., \hat{\beta}^{(e)}) = \underset{\alpha, \beta^{(i)} \dots, \beta^{(e)}}{\operatorname{ang min}} \sum_{i=1}^{n} (y_i - \alpha - \beta^{(i)} x_i^{(i)} - ... - \beta^{(e)} x_i^{(e)})^2, \\ \text{alphyeet to } \sum_{i=1}^{n} \beta^{(i)} = 1, \ \beta^{(i)} \ge 0, \ i = 1, ..., n. \end{cases}$$

$$(5)$$

Model parameters  $(\alpha, \beta^{(i)}, ..., \beta^{(ii)})$  estimated using unconstrained (3) and constrained least squares techniques (5) represent average factor exposures in the estimation window—time interval i=1,...,N. However, the factor exposures typically change in time. For example, on active trading of a portfolio of securities can lead to significant changes in its exposures to market indices within the interval. Detecting such dynamic changes, even though they happened in the past, recreasents a very important lack.

0 In order to estimate dynamic changes in factor exposures, a moving window ecohologic is typically applied. For example, in RBSA model (4), the exposures at any moment of time t are determined on the basis of solving (5) using a window of K portfolio returns [t = (K - 1), ..., t] and the returns on asset slass indices over the same time period (as described, for example, in 5. Sharpe, William F., Asset Allocation: Management Style and 5. Externance Measurement. The Journal of Portfolio Management, Winter 1992, pp. 7-19):

$$\begin{cases} (\hat{\alpha}_{r}, \hat{\beta}_{i}^{(0)}, ..., \hat{\beta}_{i}^{(n)}) = \underset{\alpha_{n} \beta^{(n)} \dots \beta^{(n)}}{\text{and } \min} \sum_{i=0}^{n-1} (y_{i-i} - \alpha - \beta^{(i)} x_{i-i}^{(i)} - ... - \beta^{(n)} x_{i-i}^{(n)})^{2}, \\ \text{subject to } \sum_{j=1}^{n} \beta^{(j)} = 1, \ \beta^{(j)} \ge 0, \ j=1, ..., n, \end{cases}$$
(6)

By moving such estimation window forward period by period, dynamic changes in factor exposures can be approximately estimated.

- The moving window technique described above has its limitations and deficiencies. The problem setup assumes that exposures are constant within the window, yet it is used to celimate their changes. Reliable estimates of model parameters can be obtained only if the window is sufficiently large which makes it impossible to sense changes that occurred within a day or a mouth, and, therefore, such technique can be applied only in cases where
- 25 parameters do not show marked absages within it: (α, ρ<sub>s</sub><sup>(1)</sup>, ..., ρ<sub>s</sub><sup>(1)</sup>) π count, t − (K − 1) ≤ κ ≤ ε. In addition, such approach fails to identify very quick, abrupt changes in investment portfolio exposures that can occur due to trading.

WO 83/096254 PCY/ISB3/15325

In situations, where detecting dynamic exposures represents an important task, the widow technique is inadequate, and a fundamentally new approach to estimating multi-factor models with changing properties are required. It is just the intent of this patent to fill in this gap.

#### B. The dynamic RBSA model

The multi-factor BISA model (4), as well as the CAPM (1) and APT once (2), are, in their casenine, linear regression models with constant regression coefficients  $(\alpha, \beta^{(1)}, ..., \beta^{(n)})$ .

10 In order to monitor a particular for quick changes in investment allocation or investment style, deviations from investment mandate, etc., a dynamic regression RBSA model is needed to represent the time series of portfolio returns y<sub>i</sub> as dynamically changing linear combination of a finite number n of time series of basic factors x<sub>i</sub> = (x<sub>i</sub><sup>(1)</sup>, ..., x<sub>i</sub><sup>(n)</sup>)<sup>T</sup> with unknown real-valued factor exposures β<sub>i</sub> = (β<sub>i</sub><sup>(1)</sup>, ..., β<sub>i</sub><sup>(n)</sup>)<sup>T</sup> and an unknown auxiliary term α<sub>i</sub>. However, in the RBSA model, both the factor exposures and the intercepts are subject to appropriate constraints (α<sub>i</sub>, β<sub>i</sub>) ∈ Z, in the simplest case, the linear ones Σ<sup>(n)</sup>, β<sup>(n)</sup> = 1, β<sup>(n)</sup> ≥ 0.

$$\begin{cases} y_i = \alpha_r + \sum_{i=1}^{n} g_i^{(i)} x_i^{(i)} + e_i = \alpha_i + \beta_i^T \mathbf{x}_j + \hat{e}_i, \\ (\alpha_r, \beta_r) \in Z, \end{cases}$$

$$(7)$$

where s, is the residual model inaccuracy treated as white noise.

26) Note that unlike (5) and (6), the model (7) assumes that factor exposures are changing in every period or time interval ε. The present invention specifies constraints (α, β, ) ∈ Z adequate to most typical problems of financial management, and describes a general way of extinuing dynamic multi-factor models under those constraints.

# C. Insufficiency of existing methods of optimating dynamic linear models

### Plexible Least Squares (FLS)

A method of unconstrained parameter estimation in dynamic linear regression models was suggested by Kaiaba and Teafatsion under the name of Flexible Least Squares (FLS) method, as described, for example, in Kalaba, R., Teafatsion, L., <u>Time-Varving Linear Regression</u> via
